

CMPSC 461: Programming Language Concepts

Assignment 1. Due: Sep. 12, 11:59PM

For this assignment, you need to submit your solution to **Gradescope**. **Except Problem 1, a solution without detailed steps or explanation will receive ZERO points.**

Problem 1 [6pt] Add parentheses to the following lambda terms so that the grouping of sub-terms becomes explicit. For example, the term $\lambda x. x \lambda y. y$ with parentheses is $\lambda x. (x (\lambda y. y))$.

- a) (3pt) $\lambda x. \lambda y. z x y$
- b) (3pt) $\lambda x. \lambda y. (\lambda x. x) y \lambda z. x y$

Problem 2 [6pt] Fully evaluate the following λ -term so that no further β -reduction is possible.

$$(\lambda x. (\lambda y. y y) x) y \lambda x. x$$

Problem 3 [10pt] Another way of defining addition on Church numbers is the following:

$$+ \triangleq \lambda n_1 n_2 f z. (n_1 f (n_2 f z))$$

Show that $(+ \underline{2} \underline{2}) = \underline{4}$ under Church encoding, where $\underline{n} \triangleq \lambda f z. f^n z$.

Problem 4 [12pt] Using the pure λ -calculus, we can encode a pair of λ -terms as where a term PAIR takes three λ -terms a, b, p and applies p to a and b . That is, we can define PAIR as $(\lambda a b p. p a b)$.

- a) (4pt) Based on this definition, we can encode function RIGHT as $\text{RIGHT} \triangleq \lambda p. (p (\lambda t f. f))$. Show that under such encoding, $\text{RIGHT} (\text{PAIR } x y)$ evaluates to y .
- b) (4pt) Try to define a function LEFT in λ -calculus so that given a pair, it returns the first term in the pair. For example, $\text{LEFT} (\text{PAIR } x y)$ should evaluate to x under your encoding.
- c) (4pt) Try to define a function REPLACE in λ -calculus so that given a pair, it “replaces” the second component with the first component in a pair. For example, $\text{REPLACE} (\text{PAIR } x y)$ should evaluate to $(\text{PAIR } x x)$ (or some equivalent term under α/β -reduction).

Problem 5 [16pt] In the lecture, we have used the pure λ -calculus to construct natural numbers and encoded some operations on them. In such encoding, a number n is encoded as a function $\lambda f z. f^n z$ (denoted as \underline{n}). In this problem, we will define more useful operations on numbers. If you get stuck in any question, try to proceed by assuming the previous function is properly defined. You can reuse any encoding given in lectures and previous questions.

- a) (4pt) Define a function ISZERO in λ -calculus, so that given a number \underline{n} , it returns TRUE (the encoding of true) if $\underline{n} = \underline{0}$; FALSE (the encoding of false) if $\underline{n} \neq \underline{0}$. Hint: try to define two terms so that applying the second term multiple times to the first term returns FALSE; otherwise, the application returns TRUE.
- b) (4pt) Define a function PRED in λ -calculus, so that given a number \underline{n} , the function returns its predecessor, assuming the predecessor of $\underline{0}$ is $\underline{0}$. Hint: follow the idea in Problem 5a. You might need to use PAIR.
- c) (4pt) Use your encoding of PRED to define a subtraction function MINUS, so that $\text{MINUS } \underline{n_1} \underline{n_2}$ returns $\underline{n_1 - n_2}$ when $n_1 \geq n_2$, and $\underline{0}$ otherwise.
- d) (4pt) Based on what you have encoded so far, and the Boolean encodings in the lecture, define an equality test, called EQUALS on two numbers, so that it returns TRUE when two numbers are equal, and FALSE otherwise.
